(54) Title: FLOW CONTROL DEVICE

(57) Abstract: A flow control device comprises an outer sleeve (13) having at least one aperture (14) through its wall, an inner sleeve (15) having at least one aperture (16) through its wall and means for providing relative sliding movement of the sleeves between "open" positions allowing variable flow of fluid through the apertures of the sleeves and "closed" positions, characterised by a pressure-reducing region (22) arranged to reduce the pressure of fluid flowing through the at least one aperture of one of the sleeves.

FLOW CONTROL DEVICE

This invention relates to flow control devices, such as chokes for hydrocarbon wells.

In a hydrocarbon well, chokes control flow of fluid into production tubing from the well bore or into regions of the well bore from the production tubing. Conventionally, such
5 chokes have been simple on/off devices that merely fully opened or fully closed the production tubing. Recently, there has been a requirement for variable flow control which has given rise to particular problems. A conventional variable flow control choke is shown in the schematic drawing of Figure 1a.

10 The basic features of this device are an outer sleeve 1 and an inner sleeve 2, each having respective sets 3, 4 of apertures located about their respective circumferences. The outer sleeve 1 may be an integral part of a section of production tubing. The inner sleeve 2 is slidably moveable by means of an actuator (not shown). Figure 1a shows the location of the sleeves in a "closed" position. Figures 1b and 1c show the relative
15 positions of the sleeves in two different "open" positions – partly open and fully open, respectively. The arrows of Figures 1b and 1c represent the flow of fluid from the well bore into the production tubing via the apertures 3, 4.

Annular seals 5, 6 and 7 are located between the inner 2 and outer 1 sleeves. These
20 seals separate the annular gap between the inner and outer sleeves into chambers whilst allowing the inner sleeve to move freely. For example, there is an annular chamber 8 between seals 6 and 7, which chamber includes the apertures 3 of the outer sleeve 1.

Activation of the actuator causes the inner sleeve 2 to be moved in the direction of the arrows shown in Figure 1a. Figure 1b shows the apparatus of Figure 1a in a partially open position, wherein the apertures 4 of the inner sleeve encroach on the chamber 8, thereby opening up a flow path. In the fully open position of Figure 1c, the apertures 4 of the inner sleeve are located entirely within the chamber 8.

Various problems may be encountered with this conventional type of flow control device. For example, as the device begins to enter an "open" position, pressure on one side of the seal tends to distort the seal and extrude it in the direction of fluid flow. Therefore, in the example shown in Figure 1b, the seal 6 tends to be extruded into the apertures of the inner sleeve. Should the fluid flow be in the opposite direction (i.e. from the production tubing to the well bore), the seal tends to extrude into the annular gap between the sleeves.

Another problem with this type of flow control device is that, at the point of opening, the fluid is flowing very quickly through the apertures, and at high pressure, with the result that the seal 6 can be damaged or dragged into the apertures 4 of the inner sleeve.

The high velocity of the fluid flow in the "just open" position of Figure 1b can also cause another problem, namely that of erosion of the edges of the apertures, particularly when the fluid is contaminated with solid particles such as sand.

Yet another problem which may be encountered with conventional flow control devices is that the increase in fluid flow rate is not linear with linear movement of the tube and

so accurate variable flow control is difficult, especially when low flow rates are required.

In accordance with a first aspect of the invention there is provided a flow control device
5 comprising an outer sleeve having at least one aperture through its wall, an inner sleeve
having at least one aperture through its wall and means for providing relative sliding
movement of the sleeves between "open" positions allowing variable flow of fluid
through the apertures of the sleeves and "closed" positions, characterised by a pressure-
reducing region arranged to reduce the pressure of fluid flowing through the at least one
10 aperture of one of the sleeves.

The provision of a pressure-reducing region reduces the risk of damage of the seal 6 and
reduces the likelihood of it being dragged into the apertures of the sleeve. Furthermore,
erosion of the apertures is reduced.

15

According to a second aspect of the invention, there is provided a flow control device
comprising an outer sleeve having at least one aperture through its wall, an inner sleeve
having at least one aperture through its wall, means for providing relative sliding
movement of the sleeves between "open" positions allowing variable flow of fluid
20 through the apertures of the sleeves and "closed" positions and a sealing arrangement
between the inner and outer sleeves comprising at least one seal, characterised by seal
bypass means arranged to permit a portion of fluid to seep around the seal so that the
fluid pressure acting on a region of the seal is reduced.

The provision of a seal bypass reduces the likelihood of extrusion of the seal which was hitherto encountered. As the fluid seeps around the seal, the pressure on the opposite sides of the seal tends to equalise.

- 5 According to a further aspect of the invention, there is provided a flow control device comprising an outer sleeve having at least one aperture through its wall, an inner sleeve having at least one aperture through its wall and means for providing relative sliding movement of the sleeves between "open" positions allowing variable flow of fluid through the apertures of the sleeves and "closed" positions, characterised in that an edge
10 region of the at least one aperture of one of the sleeves includes erosion resistant means.

The provision of an erosion resistant means prolongs the lifetime of the flow control device. Preferably the erosion resistant means includes tungsten.

- 15 A further aspect of the invention comprises the provision of tapered edge regions for the apertures of the sleeves, also for the purpose of reducing erosion.

- According to yet another aspect of the invention there is provided a flow control device comprising an outer sleeve having a set of apertures through its wall, an inner sleeve
20 having a set of apertures through its wall and means for providing relative sliding movement of the sleeves between "open" positions allowing variable flow of fluid through the apertures of the sleeves and "closed" positions, characterised in that one set of apertures includes an aperture extending beyond the others in the direction of opening movement.

The provision of the extended aperture enables low flow rates to be achieved when the device enters a "just open" position.

Preferably the shape, size and spacing of the apertures is arranged to provide a constant
5 percentage change of the velocity co-efficient characteristic of the fluid with linear movement of the inner sleeve.

The invention will now be described, by way of example, with reference to the accompanying drawings, in which:-

10

Figures 1a-1c are schematic cross sectional views of a conventional flow control device in closed and open positions;

Figure 2 is a schematic diagram showing an arrangement of flow control devices in a
15 subsea well bore;

Figure 3a is a schematic cross sectional view of apparatus constructed according to various aspects of the invention;

20 Figure 3b is a more detailed view of part of the apparatus of Figure 3a;

Figures 3c-3e illustrate the apparatus of Figure 3a at various stages of opening;

Figure 4 is a perspective view of the apparatus of Figure 3; and

Figure 5 illustrates graphically the change in flow rate and pressure drop achievable with the apparatus of Figure 3.

Like reference numerals apply to like parts throughout the specification.

5

With reference to Figure 2, there is shown a typical arrangement of a well bore, indicated generally by the reference numeral 9, with a number of branches 9a, 9b. Production tubing 10 extends from the mouth of the bore to oil reservoirs. The space between the tubing and the well bore is sealed at points along its length by means of devices 11 known as packers. Interposed between adjacent packers are chokes 12 which are each operated by actuators (not shown). In use, oil or other hydrocarbon fluids enter the production tubing 10 through the apertures in the choke devices 12, if open. The selection and operation of the motors associated with the choke actuators is carried out by operator selection by means of a surface control display. Sensors (also
15 not shown) may be employed to provide the operator with accurate information regarding the position and condition of the chokes 12.

Figure 3a illustrates a choke 12, or flow control device, constructed according to the various aspects of the invention. This flow control device has the same basic features as
20 that shown in Figures 1a-1c, namely an outer sleeve 13 having a set 14 of apertures, an inner sleeve 15 having a set 16 of apertures, a sealing arrangement 17, 18, 19 and an actuator (not shown) arranged to move the inner sleeve 15 relative to the outer sleeve 13. The arrangement of the seals 18 and 19 defines an annular chamber 20, between the sleeves, incorporating the set 14 of apertures of the outer sleeve. Figures 3a-3e illustrate

the principles behind the inventive features of the flow control device and are not intended to accurately reflect the dimensions of an actual device. For example, it is unlikely that the annular seal 17 would be as close in proximity to the seal 18 as is shown in the drawings.

5

In accordance with a first aspect of the invention there is provided a pressure-reducing region in the form of an annular insert 21. The annular insert 21 is interposed between the seal 18 and the outer sleeve 13. The insert 21 forms a region of reduced size in the form of a narrow annular passage 22 in front of the seal 18. The annular insert 21 is shown in the more detailed drawing of Figure 3b, as is one 23 of a set of grooves scored
10 into the outer surface of the inner sleeve 15. The grooves 23 are located just before the apertures 16 of the inner sleeve 15 in the direction of opening movement. The function of both the annular insert 21 and the grooves 23 will be described later in this specification.

15

Another feature of the choke of Figure 3a is that the apertures 16 of the inner sleeve 15 are of different shapes and sizes. At least one 24 of the apertures of this set 16 extends beyond the others in the direction of opening movement of the flow control device, which direction is shown by the arrows.

20

Referring now to Figure 3c, this shows commencement of an opening operation by the actuator, which is moving the inner sleeve 15 in the direction shown in the arrows. In this drawing the grooves 23 bridge the seal 18 and are now impinging on the chamber 20, which chamber includes the apertures 14 of the outer sleeve 13. Thus, hydrocarbon

fluid entering the chamber 20 from the well is permitted to seep around the grooves, bypassing the seal 18, even though the choke 12 has not attained an "open" position. This has the effect of balancing fluid pressure on both sides of the seal 18 prior to the flow control device entering an open position, thus reducing the problem of extrusion of the seal, which was hitherto caused by high pressure of the inflowing fluid acting on this seal.

Figure 3d shows the flow control device entering an open position. The extended aperture 24 of the inner sleeve 15 has just moved past the seal 18 and encroaches slightly on the chamber 20, thus permitting a small amount of fluid to flow into the bore of the inner sleeve 15. Thus, a low rate of fluid flow through the flow control device is achievable. This was more difficult with the conventional chokes in which the apertures were of the same shape and size and were aligned; small changes in flow rate could only be achieved by minute deflections of the inner sleeve, which was very difficult owing to actuators being relatively crude positioning devices. In practice, there is usually more than one extended aperture 24, typically located at diametrically opposite points of the inner sleeve 15.

Prior to entering the aperture 24 of the inner sleeve 15, fluid entering the chamber 20 from the well is directed into the small annular passage 22 provided by the annular insert 21. The dimensions of the annular passage 22 are chosen so that a large proportion of the pressure of the inflowing fluid is dropped along the passage, that is to say there is a pressure differential between the ends of the passage. Therefore, fluid entering the inner sleeve 15 is at a lower pressure than was hitherto encountered with a

conventional choke. This feature prevents the seal 18 being damaged or dragged into the apertures and also reduces erosion. The radial dimensions of the passage 22 need to be large enough, however, to prevent blockage from contaminants in the fluid.

- 5 Figure 3e shows the choke in the fully open position. In this position, fluid is able to flow through all of the apertures 16 in the inner sleeve 15, thereby producing maximum achievable flow into the production tubing. It should be noted that, as the actuator moves between the positions of Figures 3d and 3e, the effective length of the annular passage 22 reduces, so that the apertures 16 of the inner sleeve 15 are gradually exposed
- 10 to increasing pressure, culminating in full exposure to the pressure of the inflowing fluid.

- Figure 4 shows the layout of the inner sleeve 15 more clearly. For illustrative purposes, the seal 18 is shown attached to the inner sleeve 15, as is the annular insert 21. The
- 15 grooves 23 are also shown, positioned in front of all of the apertures 16 in the inner sleeve 15, except for the aperture 24. A further feature of this apparatus is that the extended aperture 24 includes an erosion-resistant insert 25, typically made of tungsten. The insert 25 is secured to the inner sleeve 15 by a screw fastener 26 at one end portion and has a lip-shaped contour at the other end portion, which engages in the aperture 24.
- 20 The insert 25 is tapered around the edges of the aperture 24, thereby providing an effective tapering of the aperture, to further resist erosion. Of course, the apertures themselves could be tapered as an extra safeguard against erosion.

The curve labelled A on Figure 5 illustrates the change in flow rate achievable with the

apparatus of the invention. The flow rate is plotted against the stroke of the inner sleeve, as moved by the actuator. This change in flow rate with stroke exhibits more linear characteristics than was hitherto achievable. Furthermore, very low flow rates are achievable. Previously, there was a step between zero flow rate in the closed position
5 and the flow rate in the "just open" position. The corresponding graph of the pressure change across the apertures is also shown in the curve labelled B.

The invention is particularly suited to the control of chokes downhole in hydrocarbon wells, however it is eminently suitable for controlling the flow of fluid in general in
10 other applications.

In a hydrocarbon well, usually only the inner sleeve is moved to control flow changes. In other applications, it may be more advantageous for the outer sleeve, or even both sleeves, to be moved by actuator mechanisms.

15

The invention has been described with respect to fluid flowing from a well bore into production tubing, i.e. from the exterior of the outer sleeve to the interior of the inner sleeve. However, the invention is equally suited to controlling fluid flow in the opposite
20 sense, with either minimal or no further adaptation needing to be made. Further variations may be made without departing from the scope of the invention. For example, the annular insert need not be interposed between the seal 18 and the outer sleeve. The insert could be attached to the outer sleeve in front of the seal or else attached to the inner sleeve. The insert could even be formed with the seal as an integral

part.

As a further variation, the erosion-resistant insert could be attached to the inner sleeve by, for example, chemical bonding or could even be an integral part of the sleeve. All
5 of the apertures of the inner and/or outer sleeves could be made erosion-resistant in this manner.

CLAIMS

1. A flow control device comprising an outer sleeve having at least one aperture through its wall, an inner sleeve having at least one aperture through its wall and means for providing relative sliding movement of the sleeves between "open" positions allowing variable flow of fluid through the apertures of the sleeves and "closed" positions, characterised by a pressure-reducing region arranged to reduce the pressure of fluid flowing through the at least one aperture of one of the sleeves.
2. A device as claimed in Claim 1, in which there is an annulus between the inner and outer sleeves, the pressure-reducing region comprising a region of the annulus of reduced size.
3. A device as claimed in Claim 2, in which the region of reduced size includes a portion of the outer sleeve having a reduced inner diameter.
4. A device as claimed in Claim 2 or 3, in which the region of reduced size includes a portion of the inner sleeve having an increased outer diameter.
5. A device as claimed in any one of Claims 1 to 4, in which the effective size of the pressure-reducing region changes as the device moves between "closed" and fully "open" positions, so as to gradually expose the at least one aperture of one of the sleeves to the full pressure of the fluid.

6. A flow control device comprising an outer sleeve having at least one aperture through its wall, an inner sleeve having at least one aperture through its wall and means for providing relative sliding movement of the sleeves between "open" positions allowing variable flow of fluid through the apertures of the sleeves and "closed" positions and a sealing arrangement between the inner and outer sleeves comprising at least one seal, characterised by seal bypass means arranged to permit a portion of fluid to seep around the seal so that the fluid pressure acting on a region of the seal is reduced.
7. A device as claimed in Claim 6, in which the seal bypass means comprises at least one groove in the inner sleeve.
8. A device as claimed in Claim 7, in which the at least one groove has a length exceeding that of the face of the seal engaging the inner sleeve.
9. A device as claimed in Claim 6, 7 or 8, in which the seal bypass means is located on the inner sleeve before the at least one aperture of the inner sleeve in the direction of opening movement.
10. A flow control device comprising an outer sleeve having at least one aperture through its wall, an inner sleeve having at least one aperture through its wall and means for providing relative sliding movement of the sleeves between "open" positions allowing variable flow of fluid through the apertures of the sleeves and "closed" positions, characterised in that an edge region of the at least one aperture of one of the

sleeves includes erosion resistant means.

11. A device as claimed in Claim 10, in which the erosion resistant means includes tungsten.

12. A device as claimed in Claim 10 or 11 in which the erosion resistant means comprises a layer of tungsten attached to the sleeve.

13. A device as claimed in Claim 10 or 11, in which the erosion resistant means comprises a layer of tungsten detachably fixed to the sleeve.

14. A flow control device comprising an outer sleeve having at least one aperture through its wall, an inner sleeve having at least one aperture through its wall and means for providing relative sliding movement of the sleeves between "open" positions allowing variable flow of fluid through the apertures of the sleeves and "closed" positions, characterised in that the at least one aperture of one of the sleeves has a tapered edge region.

15. A flow control device comprising an outer sleeve having a set of apertures through its wall, an inner sleeve having a set of apertures through its wall and means for providing relative sliding movement of the sleeves between "open" positions allowing variable flow of fluid through the apertures of the sleeves and "closed" positions, characterised in that one set of apertures includes an aperture extending beyond the others in the direction of opening movement.

16. A flow control device comprising an outer sleeve having a set of apertures through its wall, an inner sleeve having a set of apertures through its wall and means for providing relative sliding movement of the sleeves between "open" positions allowing variable flow of fluid through the apertures of the sleeves and "closed" positions, characterised in that the apertures are arranged so that the rate of fluid flow has a predetermined relationship with the position of the sleeves.

17. Production tubing including a flow control device as claimed in any preceding claim.

18. A hydrocarbon well including a flow control device as claimed in any preceding claim.

Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☐ Claims Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:

2. ☐ Claims Nos.:
because they relate to parts of the International Application that do not comply with the prescribed requirements to such an extent that no meaningful International Search can be carried out, specifically:

3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

see additional sheet

1. ☐ As all required additional search fees were timely paid by the applicant, this International Search Report covers all searchable claims.

2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.

3. ☐ As only some of the required additional search fees were timely paid by the applicant, this International Search Report covers only those claims for which fees were paid, specifically claims Nos.:

4. ☒ No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:
1-5, 17, 18

Remark on Protest

- ☐ The additional search fees were accompanied by the applicant's protest.
☐ No protest accompanied the payment of additional search fees.

FURTHER INFORMATION CONTINUED FROM PCT/ISA/ 210

This International Searching Authority found multiple (groups of) inventions in this international application, as follows:

1. Claims: 1-5,17,18

Flow control device comprising a pressure-reducing region

2. Claims: 6-9

A flow control device comprising a seal bypass means

3. Claims: 10-13

A flow control device comprising erosion resistant means

4. Claim : 14

A flow control device comprising a tapered region

5. Claims: 15,16

A flow control device comprising a set of apertures extending beyond the others, having a predetermined relationship with the position of the sleeve.
